**ABSTRACT**

**Motivation:** Nanopore sequencing may be the next disruptive technology in genomics, owing to its ability to detect single DNA molecules without prior amplification, lack of reliance on expensive optical components, and the ability to sequence long fragments. The MiniON\(^\text{TM}\) from Oxford Nanopore Technologies (ONT) is the first nanopore sequencer to be commercialized and is now available to early-access users. The MiniION\(^\text{TM}\) is a USB-connected, portable nanopore sequencer that permits real-time analysis of streaming event data. Currently, the research community lacks a standardized toolkit for the analysis of nanopore datasets.

**Results:** We introduce **poretools**, a flexible toolkit for exploring datasets generated by nanopore sequencing devices from MiniON\(^\text{TM}\) for the purposes of quality control and downstream analysis. Poretools operates directly on the native FAST5 (an application of the HDF5 standard) file format produced by ONT and provides a wealth of format conversion utilities and data exploration and visualization tools.

**Availability and implementation:** Poretools is an open-source software and is written in Python as both a suite of command line utilities and a Python application programming interface. Source code is freely available in Github at [https://www.github.com/arq5x/poretools](https://www.github.com/arq5x/poretools)

**Contact:** n.j.loman@bham.ac.uk and aaronquinlan@gmail.com

**Supplementary information:** An iPython notebook demonstrating the functionality of poretools is in Github. Complete documentation is available at [http://poretools.readthedocs.org](http://poretools.readthedocs.org).

**1 INTRODUCTION**

DNA sequencing with biological nanopores was proposed almost 20 years ago (Church et al., 1995). This approach relies on the direct electrical detection of single DNA strands in contact with an individual pore. Single molecule detection and the absence of a prior amplification step means that extremely long fragments can be sequenced without any loss in quality. In May 2014, Oxford Nanopore Technologies released MiniION\(^\text{TM}\), the first commercially available nanopore DNA sequencing device. MiniION\(^\text{TM}\) is noteworthy for its portability, size (around the software running as a cloud service. The resulting files for each sequenced read are stored in ‘FAST5’ format, an application of the HDF5 format. However, at present, no specific software is available to facilitate downstream analyses starting with this file format.

**2 FEATURES AND METHODS**

We have developed **poretools**, an open-source software toolkit that addresses the pressing need for methods to manipulate the FAST5 format and permit explorations of the raw nanopore event data and the resulting DNA sequences. Poretools provides an extensive set of data analysis methods that operate directly on either a single FAST5 file or a set of files from one or more sequencing runs. A Python programming library is provided to facilitate access to the FAST5 file structure and enable other researchers to extend the tools and create new analytical methods. In the following sections, we summarize the functionality currently available in poretools.

2.1 **Format conversion**

The most fundamental functionality provided by poretools is the ability to convert the output data resulting from a MinION run from HDF5/FAST5 format to either FASTA or FASTQ format to facilitate analyses with sequence alignment and/or assembly software. This is accomplished with the `fasta` and `fastq` commands in the poretools suite.

```
poretools fasta /path/to/fast5/example.fast5
poretools fastq /path/to/fast5/example.fast5
```

At the time of writing, each MinION run generates individual HDF5/FAST5 files for each sequenced read. Consequently, there are often tens of thousands of individual files that must be stored for a single experiment. Poretools provides two different strategies for facilitating the analysis of such datasets. The first approach allows one to execute a `poretools` command on an entire directory of FAST5 files.

```bash
poretools convert /path/to/fast5 /path/to/output/convert.fast5
```
There is a need to visualize MinION™ run performance to assess its quality and troubleshoot different fragmentation and library preparation strategies. Poretools provides two utilities, `hist` and `yield_plot`, that characterize the fragment size distribution and display a collector’s curve of the overall sequencing yield, respectively. Example commands are provided here, with corresponding figures shown (Fig. 1A and B).

### 2.2 Data exploration and visualization

#### Table 1. Summary of currently supported operations in poretools

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>combine</td>
<td>Combine a set of FAST5 files in a TAR archive.</td>
</tr>
<tr>
<td>events</td>
<td>Extract each nanopore event for each read.</td>
</tr>
<tr>
<td>fasta</td>
<td>Extract FASTA sequences from a set of FAST5 files.</td>
</tr>
<tr>
<td>fastq</td>
<td>Extract FASTQ sequences from a set of FAST5 files.</td>
</tr>
<tr>
<td>hist</td>
<td>Plot read size histogram for a set of FAST5 files.</td>
</tr>
</tbody>
</table>

Fig. 1. Example poretools visualizations from a set of FAST5 files generated by a single MinION™ run. Panel A shows a histogram of read lengths. Panel B shows a collector’s curve of reads over time. Panel C shows an example squiggle plot of detected event transitions originating from MinION™
nanopore during the event. The *squiggle* utility permits visualization of this information (Fig. 1C). The Oxford Nanopore base-calling software uses a Hidden Markov Model to predict a fragment’s sequence based on this event data. We anticipate that the *events* utility (and others) will help developers explore improved base-calling strategies.

2.3 Python library for data analysis

The utilities provided in the *poretools* suite will inevitably prove to be insufficient for every analysis that a researcher wishes to conduct. Recognizing this, we have developed a Python programming interface that researchers can use to directly access the sequence data, the raw nanopore event data and other metadata (e.g. the flowcell and run identifiers) contained in one or more FAST5 files. To demonstrate of the Python interface, the following code reports the start time, the specific nanopore and the based-called sequence for each FAST5 file in a sequencing run.

```python
from poretools import Fast5FileSet
fast5s = Fast5FileSet("/path/to/fast5/files/")
for fast5 in fast5s:
    start = fast5.get_start_time()
    porenun = fast5.get_channel_number()
    fq = fast5.get_fastq()
    print porenun, start, fq.seq, fq.qual
fast5.close()
```

3 DISCUSSION

The *poretools* software helps solve pressing requirements for analysis of nanopore sequencing data. By focusing on the Python development environment and adopting expected interface conventions as popularized by other popular bioinformatics tools such as *samtools* (Li *et al.*, 2010) and *bedtools* (Quinlan *et al.*, 2009), we expect that users will be able to rapidly exploit the functionality offered by this software. We anticipate that other toolkits will become available written in other programming languages. Further efforts are required for downstream analysis for common tasks including alignment and *de novo* assembly of both event and base-called sequence data from this platform.

ACKNOWLEDGEMENTS

The authors would like to express their gratitude to the employees of ONT for assistance during the MinION Access Programme™, with particular thanks to Zoe McDougall, Clive Brown, Daniel Turner, Stephanie Brooking, Roger Pettett and Stuart Reid. We would like to thank members of the MinION user community who have tested *poretools* and continue to provide feedback and bug reports.

**Funding**: N.J.L. is funded by a Medical Research Council Special Training Fellowship in Biomedical Informatics. A.R.Q. was supported by the NIH (NGHRI; 1R01HG006693-01).

**Conflict of interest**: none declared.
